This section provides an overview of the Sage Employee Self Service (ESS) advanced customization interfaces, which includes authentication integration and data access.

## Requirements

All interfaces available for advanced customization are currently installed by default on Sage Employee Self Service (ESS) servers. You will need a working server environment to use the documented interfaces. Refer to the [Sage Employee Self Service Installation and Setup Guide](#) for detailed system requirements.

## Customization Interfaces

Employee Self Service contains various customization options that allow for changes to the look, feel, and functionality of the product through screens available from within the product or manipulation of files through third-party tools. Changes to items such as logos, graphics, menus, documents, colors, fonts, security, and workflow settings that do not require any programming are considered “simple” customization options. These are not covered in the current document.

To allow business partners and customers to extend the functionality of Sage Employee Self Service, we currently provide interfaces for “advanced” customization.

- The ESS single sign-on interface (SSOI) allows the integration of other existing or custom applications into the ESS application framework eliminating the need for self-service users to sign on to connected applications once they have been authenticated through ESS.

A custom application can use SSOI methods to retrieve information about the Sage HRMS employee currently logged into ESS as well as information necessary to access the Sage HRMS and ESS databases currently used by ESS.

- With the information retrieved from SSOI, a third-party application can then use the .NET Data Access API to allow other applications to connect to Sage HRMS data from ESS servers. It supports ADO and ADO.NET read and write access to encrypted and unencrypted databases.

A standard Microsoft SQL OLEDB provider can be used to access data stored in the ESS database as this database is either a Microsoft SQL Server 2005/2008 or SQL Server 2005/2008 Express Edition (SQL Express) database, depending on the options chosen during the ESS product installation.

- View Builder has been extended to include custom data created through Custom Details in Sage HRMS. A Data Sync Web Service enables external data source and third party applications to be integrated with Custom Details data in Sage HRMS via an XML file and a Custom Data Provider Interface can integrate directly into the View Builder, real-time, to retrieve and expose data available for views.

# ESS Single-Sign-On Interface (SSOI)

---

## Introduction

The ESS Single-Sign-On Interface (SSOI) is a web service that allows access to ESS information for other web applications that were invoked using custom URL references configured through the customization pages on the ESS administrator setup.

## Requirements

The SSOI provides a way for other applications to retrieve Sage HRMS and Sage Employee Self Service data as well as some information associated with the user session. The SSOI is an integral part of Sage Employee Self Service.

## Features

The SSOI provides the following information to a third-party application:

- **Employee logon**

The user name (or “logon”) that was used by the employee to access ESS. This information may be used to integrate authentication in ESS with authentication in a third-party application.

- **Suite Employee Key information**

A third-party application can retrieve additional data related to the employee from both Sage HRMS and the SQL or SQL Express database used by ADS by using the “key information” (employee id and the company code) supplied by the SSOI. The key is derived from the information for the user that was logged on to ESS when the SSOI data was collected.

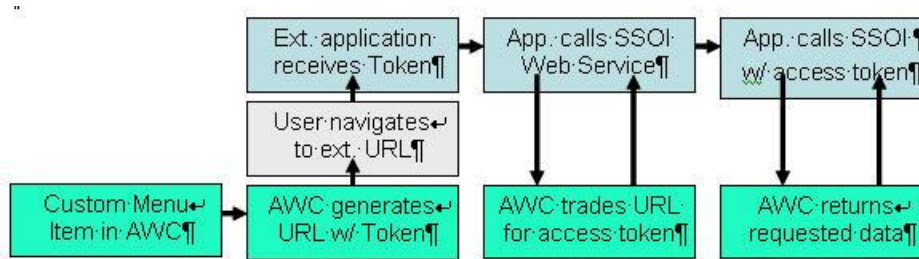

- **Connection strings**

The SSOI provides methods to retrieve the connection strings used by ESS to connect to both Sage HRMS and the SQL or SQL Express database used by ADS. Credentials (user name and password) needed to access the database will not be returned for security reasons and will need to be supplied by the third-party application.

## Using ESS SSOI

In order to use SSOI in your application, you need the ability to consume a Web service. The SSOI requires multiple steps or calls when leaving an ESS application and navigating to a third-party application to prevent abuse and avoid vulnerabilities in the hand-over process. Refer to the Pre-Installation section of the [ESS Installation and Setup Guide](#) for Information Security Recommendations for Public Access Workstations.

A diagram illustrating the flow of a typical SSOI hand-over sequence can be found below:

Please note that the top row in the diagram contains actions initiated by the third-party application, the center row contains user actions, and the bottom row shows ESS functions.

To use the single-sign-on feature, you first have to log on to ESS as the master user and set up external URLs with the single-sign-on feature enabled. These URLs can then be used to create custom ESS menu entries. When ESS generates the URLs that are used for the menu entries and it encounters an external URL where the SSOI feature is enabled, it appends a string in the form “URLToken=<GUID>” to the external URL. At this time information related to the current user will be stored by ESS in a cache.

When a user attempts to navigate to this URL, an HTTP(s) request to the third-party application follows. The third-party application can then retrieve the URL token and call the SSOI Web service to exchange this URL token for an “access token.” Immediately after this step is completed, the URL token itself is no longer valid.

This is done to prevent, for example, another user or hacker who may be able to see or intercept the URL that is passed through the client from “re-using” the token. All subsequent calls only involve communications between the third-party application and ESS, but not the client. This also means that the aforementioned communication needs to take place over a “secure channel,” either over a physically secured Intranet or using HTTPS so that the data transmitted cannot be easily intercepted.

Once the third-party application has the access token, it needs to be supplied on all subsequent calls that retrieve any ESS information through the SSOI.

## Code Reference

The Web Service currently supports the methods listed below. The signatures are shown in C# syntax to improve readability. You may also request the following URL to browse the most current web service description:

`http://<ESSServer>/selfservice/SSOI/AbraWorkForceConnSSI.asmx`

### [WebMethod]

```
public bool IsValidToken(string sURLToken)
```

This call allows you to verify whether the string argument passed into the call represents a currently valid URL token.

**[WebMethod]**

```
public string ProcessURLToken(string sURLToken)
```

You must call this method immediately after receiving the URLToken. This call will “exchange” the URL token that was passed through the client machine and return an access token that needs to be used for subsequent calls. This call immediately invalidates the URLToken to prevent abuse (for example, attempts to request the same URL again from another client).

**[WebMethod]**

```
public string GetEmpID(string sAccessToken)
```

This method returns the employee ID of the user who is or was logged on to ESS. The value returned corresponds to the employee ID field in Sage HRMS.

**[WebMethod]**

```
public string GetCompany(string sAccessToken)
```

This method returns the company code for the employee associated with the user who is or was logged on to ESS. The value returned corresponds to the company code of the employee record in Sage HRMS.

**[WebMethod]**

```
public string GetSuiteConnectionString(string sAccessToken)
```

A call to this method returns the connection string that ESS uses to connect to the Sage HRMS database in question. The connection string will not contain a user name or password. These must be appended by the third-party application before using this connection string in conjunction with the API.

**[WebMethod]**

```
public string GetSQLConnectionString(string sAccessToken)
```

A call to this method returns the connection string that ESS uses to connect to its internal SQL database. The connection string will not contain a user name or password. These must be appended by the third-party application before using this connection string in conjunction with SQL OLEDB.

**[WebMethod]**

```
public string GetReturnURL(string sAccessToken)
```

This method returns a URL that can be used to navigate back to the calling ESS application. Any existing sessions may have expired and the user may be required to log back into ESS.

**[WebMethod]**

```
public string GetLoginName(string sAccessToken)
```

This method returns the ESS logon / user name belonging to the ESS user who initiated the SSOI request at the time when the SSOI link was generated. Keep in mind that ESS users can change their logon credentials while they are logged on.

Additional Web methods and a COM wrapper may be made available in a subsequent version of SSOI.

# .NET Data Access API Interface

---

## Introduction

To provide access to Sage HRMS data for third-party applications, ESS includes a service called “Abra Data Service” (ADS). This service allows access to encrypted FoxPro databases using the credentials configured for ESS and also supplies third-party applications with additional virtual, computed key columns in the Sage HRMS database to allow reconciliation of the ESS and Sage HRMS data.

Sage offers an API for third-party applications using the Microsoft .NET framework. The new API allows for efficient access to both SQL and FoxPro data in Sage HRMS.

---

**Note:** Third-party add-ons for Sage ESS users have the option to go through ADS instead of the data access APIs.

---

## Features

The API provides the following functionality:

- Common API for SQL and FoxPro queries
- Enables access to virtual key columns which provides efficient processing for SQL and FoxPro databases
- Accepts T-SQL style queries for both SQL Server and FoxPro to automatically translate FoxPro databases (for example string length literals, single-quote handling, case-sensitivity, date handling, and TRIM function conversion)
- Supports encryption when using an ADS provider with the new API
- Auto-parameterization of SQL queries. To enhance query execution times, the API automatically parameterizes SQL queries to allow re-use of SQL execution plans for queries that only differ in literal expressions.
- Utility functions such as simplified .NET data access

The new API does have some limitations. Not all SQL statements, especially SQL server functions, can be automatically translated to FoxPro and SQL. You can either avoid SQL-specific functions in your queries or create different commands for FoxPro and SQL server.

## Using the API

The API has two different access methods as follows:

- Create an instance of the class `AbraDataAdapter`. You can initialize `AbraDataAdapter` with either an existing `DataAdapter` or using command and connection parameters, similar to an `OleDbDataAdapter` or `SqlDataAdapter`.
- Directly use the static utility functions of `AbraDataAdapter`. You can directly execute the utility function, for example `AbraDataAdapter.Execute(sCommand, sConnection)`, to obtain a `DataSet`.

### Sage Employee Self Service .NET Data Access API Interface Definition

```
// Constructor
public AbraDataAdapter(IDbDataAdapter oAdapterIn)
public AbraDataAdapter(string selectCommandText, OleDbConnection selectConnection)
public AbraDataAdapter(string selectCommandText, SqlConnection selectConnection)
public AbraDataAdapter(string selectCommandText, string selectConnectionString)
public AbraDataAdapter(OleDbCommand selectCommand)
public AbraDataAdapter(SqlCommand selectCommand)
public AbraDataAdapter()
public AbraDataAdapter(bool bSQL)

// IDbDataAdapter
public IDbCommand UpdateCommand // get / set property
public IDbCommand SelectCommand // get / set property
public IDbCommand DeleteCommand // get / set property
public IDbCommand InsertCommand // get / set property

// IDataAdapter
public int Fill(DataSet dataSet)
public ITableMappingCollection TableMappings // get property
public System.Data.MissingSchemaAction MissingSchemaAction
// get / set property
```

```
public System.Data.MissingMappingAction MissingMappingAction
// get / set property

public IDataParameter[] GetFillParameters()

public DataTable[] FillSchema(DataSet dataSet, System.Data.SchemaType schemaType)

public int Update(DataSet dataSet)

// Easy-access static utility functions

public static object ExecuteScalar(IDbCommand oCmd)

public static object ExecuteScalar(string commandText, OleDbConnection connection)

public static object ExecuteScalar (string commandText, SqlConnection

public static object ExecuteScalar (string commandText, string sConnString)

public static int ExecuteNonQuery(IDbCommand oCmd)

public static int ExecuteNonQuery(string commandText, OleDbConnection connection)

public static int ExecuteNonQuery(string commandText, SqlConnection

public static int ExecuteNonQuery(string commandText, string sConnString)

public static DataSet Execute(string selectCommandText, string selectConnection)

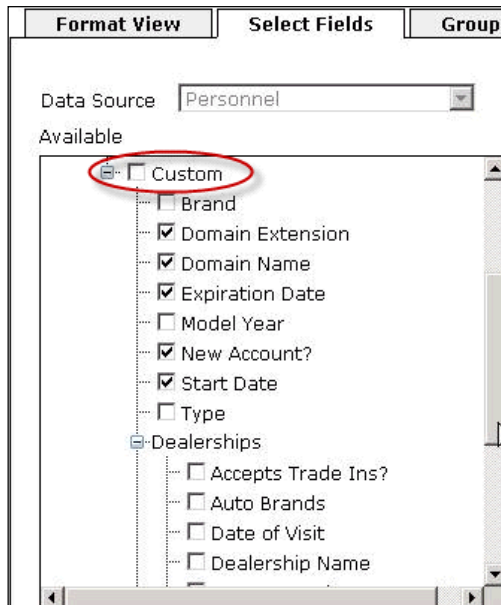

public static DataSet Execute(string selectCommandText, OleDbConnection selectConnection)

public static DataSet Execute(string selectCommandText, SqlConnection selectConnection)
```

# Exposing Custom Data in View Builder

View Builder, delivered with Sage Employee Self Service (ESS), provides the ability to deliver Sage Employee Analytics to Executives, Managers, and Employees. With the upcoming SQL release we have extended View Builder to view custom data created through Custom Details in Sage HRMS.

Any custom fields that are created in Custom Details are automatically exposed in View Builder. The figure below is an example of Custom Details data exposed in View Builder. All Custom Details data is available under a node called **Custom**.

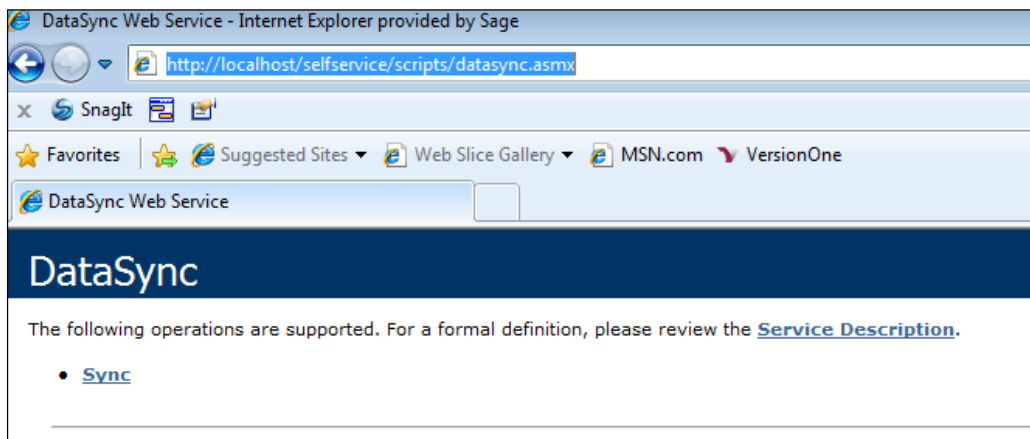

Custom data created in Custom Details can be accessed and used in View Builder in the same way as the current View Builder data is available. It can be used to select, view, filter, sort, etc. The next figures show an example of Custom Details data rendered in View Builder.

Individual Records	
<b>Aflac Services</b>	<b>SSN/SIN</b> ▾
<a href="#">View Aflac Services Records</a>	147-85-1132

Enrollment Date	New Policy?	Policy Name	Product Type
01/01/2011	True	Cancer/Specified Disease	Supplemental
01/01/2007	False	Short Term Disability	Short Term

## Custom Details Web Service/API

Another feature that has been added to Employee Self Service is the ability to populate Custom Details data by using a web service. This enables any external data source/third party application data to be integrated with Custom Details data in Sage HRMS. The web service is located in the ESS web path **http://<AppPath>/scripts/datasync.asmx**.

The **datasync.asmx** web service is made up of one supported operation: **Sync**.

The **Sync** operation has three parameters:

- **strXml**: This parameter is the xml string which contains the Custom Details data and data structure. The xml format will be discussed later in the document.
- **user** and **pwd**: The user name and password for data sync purposes is set on the ESS System Setup page (**System Administrator > System Settings > System Setup**):

Custom Data API User	
User Name	<input type="text" value="Apiuser"/>
Password	<input type="password" value="••••"/>

The top of the following figure shows the area on the DataSync window where these parameters are entered.

**DataSync**

Click [here](#) for a complete list of operations.

---

**Sync**

**Test**

To test the operation using the HTTP POST protocol, click the 'Invoke' button.

Parameter	Value
strXml:	<input type="text"/>
user:	<input type="text"/>
pwd:	<input type="text"/>

---

**SOAP 1.1**

The following is a sample SOAP 1.1 request and response. The **placeholders** shown need to be replaced with actual values.

```
POST /selfservice/scripts/datasync.asmx HTTP/1.1
Host: localhost
Content-Type: text/xml; charset=utf-8
Content-Length: length
SOAPAction: "http://tempuri.org/Sync"

<?xml version="1.0" encoding="utf-8"?>
<soap:Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema-instance" xmlns="http://tempuri.org/">
  <soap:Body>
    <Sync xmlns="http://tempuri.org/">
      <strXml>string</strXml>
      <user>string</user>
      <pwd>string</pwd>
    </Sync>
  </soap:Body>
</soap:Envelope>
```

```
HTTP/1.1 200 OK
Content-Type: text/xml; charset=utf-8
Content-Length: length

<?xml version="1.0" encoding="utf-8"?>
<soap:Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema-instance" xmlns="http://tempuri.org/">
  <soap:Body>
    <SyncResponse xmlns="http://tempuri.org/">
      <SyncResult>
        <ReturnCode>Ok or FailedAuthorization or FailedXSDInit or FailedXmlValidation or Exception</ReturnCode>
        <ResultInfo>string</ResultInfo>
      </SyncResult>
    </SyncResponse>
  </soap:Body>
</soap:Envelope>
```

---

**SOAP 1.2**

The following is a sample SOAP 1.2 request and response. The **placeholders** shown need to be replaced with actual values.

```
POST /selfservice/scripts/datasync.asmx HTTP/1.1
Host: localhost
Content-Type: application/soap+xml; charset=utf-8
Content-Length: length

<?xml version="1.0" encoding="utf-8"?>
<soap12:Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema-instance" xmlns="http://www.w3.org/2001/XMLSchema-instance" xmlns:soap12="http://schemas.xmlsoap.org/soap12/">
  <soap12:Body>
    <Sync xmlns="http://tempuri.org/">
      <strXml>string</strXml>
      <user>string</user>
      <pwd>string</pwd>
    </Sync>
  </soap12:Body>
</soap12:Envelope>
```

```
HTTP/1.1 200 OK
Content-Type: application/soap+xml; charset=utf-8
Content-Length: length

<?xml version="1.0" encoding="utf-8"?>
<soap12:Envelope xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema-instance" xmlns="http://www.w3.org/2001/XMLSchema-instance" xmlns:soap12="http://schemas.xmlsoap.org/soap12/">
  <soap12:Body>
    <SyncResponse xmlns="http://tempuri.org/">
      <SyncResult>
        <ReturnCode>Ok or FailedAuthorization or FailedXSDInit or FailedXmlValidation or Exception</ReturnCode>
        <ResultInfo>string</ResultInfo>
      </SyncResult>
    </SyncResponse>
  </soap12:Body>
</soap12:Envelope>
```

---

**HTTP POST**

The following is a sample HTTP POST request and response. The **placeholders** shown need to be replaced with actual values.

```
POST /selfservice/scripts/datasync.asmx/Sync HTTP/1.1
Host: localhost
Content-Type: application/x-www-form-urlencoded
Content-Length: length

strXml=stringuser=stringpwd=string
```

```
HTTP/1.1 200 OK
```

## XML Definition

As stated above, the Data Sync operation takes an xml string as the first input. The figure below is an example of a valid custom data xml string. The xml consists of three parts: General information, DataStructure, and Data, which will be discussed in more detail in the next sections. For the process to work, all parts must be sent in one xml file.

```

<?xml version="1.0" encoding="utf-8" ?>
- <Root>
  <XMLSchemaVersion>1</XMLSchemaVersion>
  <ExternalSourceId>Aflac</ExternalSourceId>
  <DataFeedId>DuckBenefits</DataFeedId>
  <DataRelationship>2</DataRelationship>
  <Description>Aflac Services</Description>
  - <DataStructure>
    - <Field>

  </Data>
</Root>

```

## XML General Information section

```
- <K00L>  
  <XMLSchemaVersion>1</XMLSchemaVersion>  
  <ExternalSourceId>Aflac</ExternalSourceId>  
  <DataFeedId>DuckBenefits</DataFeedId>  
  <DataRelationship>2</DataRelationship>  
  <Description>Aflac Services</Description>  
- <DataStructure>
```

1. **XMLSchemaVersion** (Type=Number Length=10 Required=Y Valid Values=Number): To support multiple versions of xml that can be sent to the web service, the xml must pass a version. This is necessary so the web service knows how to process the payload. Version one allows for bulk data insert/replace. This version does not support CRUD (Create/Update/Delete). The current version of the web service always bulk replaces the custom data on subsequent calls.
2. **ExternalSourceId** (Type=String Length=10 Required=Y Valid Values=Alpha numeric): This element is a unique identifier that identifies an external entity or third party application. For example, **Aflac** for an external entity or **BP third party app name** for a third party application.
  - **DataFeedId** (Type=String Length=14 Required=Y Valid Values=Alpha numeric): An ExternalSourceId can have multiple data feeds. The DataFeedId element allows for multiple feeds to be sent to Custom Details data in Abra HRMS. The combination of **ExternalSourceId** + "\_" + **DataFeedId** uniquely identifies an external feed in Custom Details. In the example at the top of this page, the key is **Alfac\_DuckBenefits**. When a key is established and has been used by customers, you should not change it.
  - **DataRelationship** (Type=Number Length=1 Required=Y Valid Values=1,2): Custom Details has the ability to store data as a **1 to 1** relationship, which is stored in the table **HRTKPERS**. It also has the ability to store **1 to many** relationships. In this case, each custom data feed generates a **TKMULnnn** table, where nnn is a sequential number assigned by the system. For **1 to 1** data feeds, the value for DataRelationship should be set to 1. For a **1 to many** feed, the value for DataRelationship should be set to 2.
  - **Description** (Type=String Length=50 Required=Y Valid Values=Alpha numeric): The Description element is used to show the custom data feed in a user friendly manner in View Builder.

## XML Data structure section

```

</Description>And Services</Description>
- <DataStructure>
  - <Field>
    <Title>Product Type</Title>
    <DatabaseField>PRODTYPE</DatabaseField>
    <DataType>C</DataType>
    <Length>30</Length>
    <DecimalPlaces>0</DecimalPlaces>
    <Required>Y</Required>
  </Field>
  - <Field>
    <Title>Policy Name</Title>
    <DatabaseField>POLCNAME</DatabaseField>
    <DataType>C</DataType>
    <Length>40</Length>
    <DecimalPlaces>0</DecimalPlaces>
    <Required>Y</Required>
  </Field>
  - <Field>
    <Title>New Policy?</Title>
    <DatabaseField>NUPOLICY</DatabaseField>
    <DataType>L</DataType>
    <Length>1</Length>
    <DecimalPlaces>0</DecimalPlaces>
    <Required>Y</Required>
  </Field>
  - <Field>
    <Title>Enrollment Date</Title>
    <DatabaseField>ENRLDATE</DatabaseField>
    <DataType>D</DataType>
    <Length>8</Length>
    <DecimalPlaces>0</DecimalPlaces>
    <Required>N</Required>
  </Field>
</DataStructure>
- <Data>

```

The **DataStructure section** of the xml contains the Field properties, which are used to create the Custom Details data structures. The fields are used to alter the **HRTKPERS** table or the assigned **TKMULnnn** table, depending on the DataRelationship passed in.

1. **Title** (Type=String Length=20 Required=Y Valid Values=Alpha numeric): Each field must pass a title or description, which is used to display the column header.
2. **DatabaseField** (Type=String Length=8 Required=Y Valid Values=Alpha numeric): The DatabaseField element is used to name each column in the database. Each value must be unique within the xml string.
  - **DataType** (Type=String Length=1 Required=Y Valid Values=C,N,D,L): The field structure must pass the correct data type of the field. The valid values are described as:
    - C = Character string (Abc123); any Ascii printable character
    - N = Numeric (9999999.99999)
    - D = Date (mm/dd/yyyy)
    - L = Boolean (Y,N)Any values that are not valid generate an error report that is sent back to the external application.
  - **Length** (Type=Number Length=10 Required=Y Valid Values=Number): The maximum length of the field.
  - **DecimalPlaces** (Type=Number Length=10 Required=Y Valid Values=Number): The number of decimal places. This value is only relevant if the field is a number. Any other data type ignores this element.
  - **Required** (Type=String Length=1 Required=Y Valid Values=Y,N): The Required element determines if the value is required.

## XML Data section

```

</DataStructure>
- <Data>
  - <DataRow>
    <Value name="CompanyId">CRU</Value>
    <Value name="EmpNo">1</Value>
    <Value name="PRODTYPE">Supplemental</Value>
    <Value name="POLCNAME">Cancer/Specified Disease</Value>
    <Value name="NUPOLICY">Y</Value>
    <Value name="ENRLDATE">01/01/2011</Value>
  </DataRow>
  - <DataRow>
    <Value name="CompanyId">CRU</Value>
    <Value name="EmpNo">1</Value>
    <Value name="PRODTYPE">Short Term</Value>
    <Value name="POLCNAME">Short Term Disability</Value>
    <Value name="NUPOLICY">N</Value>
    <Value name="ENRLDATE">01/01/2007</Value>
  </DataRow>
  - <DataRow>
    <Value name="CompanyId">CRU</Value>
    <Value name="EmpNo">2</Value>
    <Value name="PRODTYPE">Supplemental</Value>
    <Value name="POLCNAME">Cancer/Specified Disease</Value>
    <Value name="NUPOLICY">N</Value>
    <Value name="ENRLDATE">01/01/2009</Value>
  </DataRow>
  - <DataRow>
    <Value name="CompanyId">CRU</Value>
    <Value name="EmpNo">3</Value>
    <Value name="PRODTYPE">Hospitalization</Value>
    <Value name="POLCNAME">Hospital Care</Value>
    <Value name="NUPOLICY">1</Value>
    <Value name="ENRLDATE">01/01/2011</Value>
  </DataRow>
</Data>
</Data>

```

The XML Data section contains DataRow elements. Each DataRow element contains child elements, which contain the data for each DataRow. Every DataRow element must have at a minimum two values: **CompanyId** and **EmpNo**. Without these elements, the data cannot be linked properly to Sage HRMS. Each name attribute on the value elements must match the DatabaseField name in the DataStructure section. If a named value does not match a DatabaseField name, that value is ignored and not processed.

---

**Important!** All the data rows must be sent **every** time. This is because the process completely deletes the prior data and replaces it with the new data feed.

---

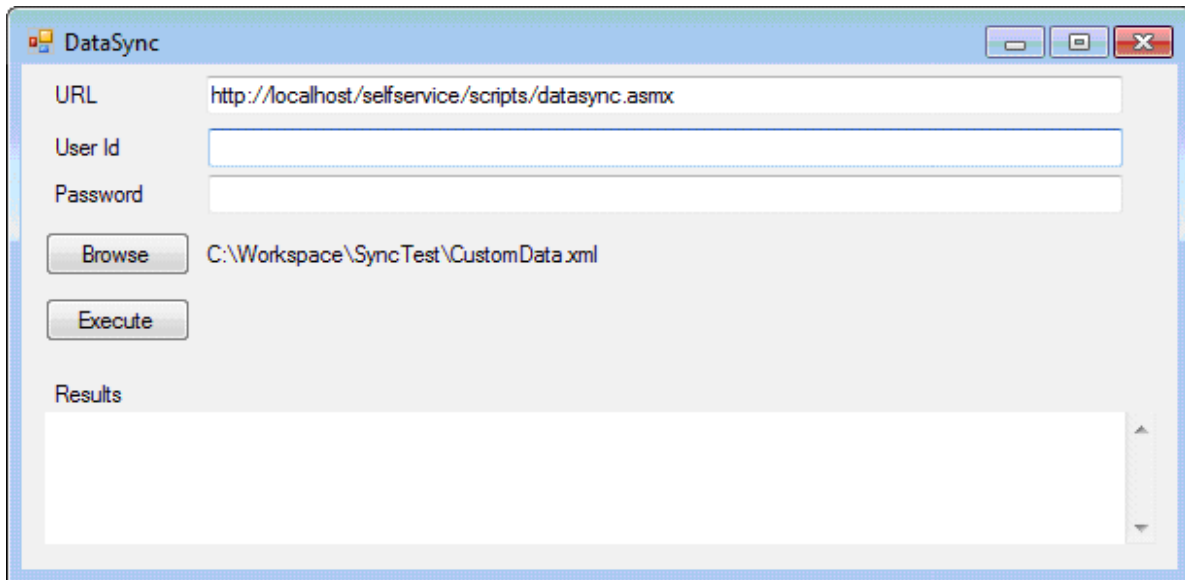

## Sample Application

A sample application, delivered with this release, calls the custom data web service. The sample application is located in a folder called **DatasyncUI** on the Desktop. The accompanying source code is located in a folder called **DatasyncUISource** on the Desktop.

---

**Note:** This is a sample application and should **not** be used for production purposes. It is distributed for the sole purpose of understanding how to implement this feature.

---

1. Point the URL to any location for the web service.
2. Enter a User Id and Password. These must match the user name and password set in ESS for the **Custom Data API User** (on the **System Setup > System Settings** page).
3. Browse to a valid **xml** file and click **Execute** to run the process.
4. The Results control displays the result of the web service call.

This sample application is a Windows-based application written in C# using Visual Studio 2010. The application code is shown below:

```

private void btnExecute_Click(object sender, EventArgs e)
{
    webBrowser.Document.Body.InnerHtml = string.Empty;
    webBrowser.Document.Write("<HTML><BODY>Running</BODY></HTML>");

    XmlDocument xmlDoc = new XmlDocument();
    xmlDoc.Load(lblFilePath.Text);
    DataSync dataSync = new DataSync();

    dataSync.Url = tbURL.Text.Trim();
    ReturnValues rv = dataSync.Sync(xmlDoc.OuterXml, tbUserId.Text, tbPassword.Text);

    string documentText = string.Empty;

    if (rv.ReturnCode == Result.Ok)
    {
        documentText = "<HTML><BODY>Success!</BODY></HTML>";
    }
    else if (rv.ReturnCode == Result.FailedAuthorization)
    {
        documentText = "<HTML><BODY>Authorization Failed!</BODY></HTML>";
    }
    else if (rv.ReturnCode == Result.FailedXSDInit)
    {
        documentText = "<HTML><BODY>XSD Initialization Failed!</BODY></HTML>";
    }
    else if (rv.ReturnCode == Result.FailedXmlValidation)
    {
        XmlDocument resultInfo = new XmlDocument();
        resultInfo.LoadXml(rv.ResultInfo);
        XmlElement rootElement = resultInfo.DocumentElement;
        XmlNodeList messages = rootElement.SelectNodes("//Error");
        string message = "<HTML><BODY>" +
messages.Item(0).SelectSingleNode("ErrorDescription").SelectSingleNode("table").OuterXml +
"</BODY></HTML>";
        documentText = message;
    }
    else if (rv.ReturnCode == Result.Exception)
    {
        XmlDocument resultInfo = new XmlDocument();
        resultInfo.LoadXml(rv.ResultInfo);
        XmlElement rootElement = resultInfo.DocumentElement;
        XmlNodeList messages = rootElement.SelectNodes("//Error");
        MessageBox.Show(messages.Item(0).SelectSingleNode("ErrorDescription").InnerText);
    }
    else
    {
        documentText = "<HTML><BODY>Unkown Status!</BODY></HTML>";
    }

    webBrowser.Document.Body.InnerHtml = string.Empty;
    webBrowser.Document.Write(documentText);
}
}

```

For flexibility, the test application's result control is a web browser control. This is because the error report returned from the web service is in HTML format.

In order to call the web service, a DataSync object has to be created. Then call the Sync method and pass in the xml and security information.

```
DataSync dataSync = new DataSync();

dataSync.Url = tbURL.Text.Trim();
ReturnValues rv = dataSync.Sync(xmlDoc.OuterXml, tbUserId.Text, tbPassword.Text);
```

The call is synchronous. When it returns, process the ReturnCode as shown below.

```
if (rv.ReturnCode == Result.Ok)
{
    documentText = "<HTML><BODY>Success!</BODY></HTML>";
}
else if (rv.ReturnCode == Result.FailedAuthorization)
{
    documentText = "<HTML><BODY>Authorization Failed!</BODY></HTML>";
}
else if (rv.ReturnCode == Result.FailedXSDInit)
{
    documentText = "<HTML><BODY>XSD Initialization Failed!</BODY></HTML>";
}
else if (rv.ReturnCode == Result.FailedXmlValidation)
{
    XmlDocument resultInfo = new XmlDocument();
    resultInfo.LoadXml(rv.ResultInfo);
    XmlElement rootElement = resultInfo.DocumentElement;
    XmlNodeList messages = rootElement.SelectNodes("//Error");
    string message = "<HTML><BODY>" +
messages.Item(0).SelectSingleNode("ErrorDescription").SelectSingleNode("table").OuterXml +
"</BODY></HTML>";
    documentText = message;
}
else if (rv.ReturnCode == Result.Exception)
{
    XmlDocument resultInfo = new XmlDocument();
    resultInfo.LoadXml(rv.ResultInfo);
    XmlElement rootElement = resultInfo.DocumentElement;
    XmlNodeList messages = rootElement.SelectNodes("//Error");
    MessageBox.Show(messages.Item(0).SelectSingleNode("ErrorDescription").InnerText);
}
else
{
    documentText = "<HTML><BODY>Unkown Status!</BODY></HTML>";
}
```

## Real-time Custom Data Provider Interface

If syncing third-party data with the Custom Details is not sufficient, it is possible to plug directly into the View Builder by implementing a specific .NET interface inside of a Class Library assembly and placing that library in the **ESS Web\bin** directory. When an ESS session is first initialized after the login, it scans this directory for custom data provider implementations and will display additional properties it finds inside of the View Builder below the **Personnel\Custom** grouping.

### Implementing the Custom Data Provider

- The Custom Data Provider implementation can expose employee-level custom data on a one-to-one or a one-to-many basis in the same way as the Custom Details Provider.
- The Custom Data Provider must be able to provide the metadata for all the custom properties of a given HRMS base entity (typically Personnel). This is what populates the View Builder tree. It also must be able to retrieve the property values for a specific employee when the view is rendered based on the primary key (Employee ID + Company Code).
- How and from where the data is retrieved is left up to the consumer of the Custom Data Provider. Note that for large result sets, the provider is invoked for every row, so performance may be impacted if some caching mechanism is not considered in place of numerous database queries.

To implement a Custom Data Provider, a .NET assembly must reference the **HRMS.Data.Custom.dll** already in the **ESS Web\bin** directory, and each provider class must implement the **HRMS.Data.Custom.IHRMSCustomDataProvider** interface. A sample provider is shown below to demonstrate how to model the two types of supported relationships to EmployeePersonnel and serve the data in View Builder.

```
using HRMS.Data.Custom;
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace TestProvider
{
    public class Provider : IHRMSCustomDataProvider
    {
        private ICustomFieldMetaData _ShirtSize;
        private ICustomFieldMetaData _PerformanceReviewDate;
        private ICustomFieldMetaData _PerformanceReviewRating;

        private void InitMetaData(string className)
        {
            // Add a 1-to-1 property for T-Shirt Size
            _ShirtSize = new CustomFieldMetaData(this);
            _ShirtSize.BaseClass = className;
            _ShirtSize.CustomFieldDataType = typeof(string);
            _ShirtSize.CustomFieldName = "ShirtSize";
            _ShirtSize.CustomFieldDisplayName = "T-Shirt Size";
            _ShirtSize.DisplayOrder = 1;
        }
    }
}
```

```

        // Add 2 one-to-many properties for Performance Reviews
        _PerformanceReviewDate = new CustomFieldMetaData(this);
        _PerformanceReviewDate.BaseClass = className;
        _PerformanceReviewDate.CustomFieldDataType = typeof(DateTime);
        _PerformanceReviewDate.CustomFieldName = "ReviewDate";
        _PerformanceReviewDate.CustomFieldDisplayName = "Performance Review Date";
        _PerformanceReviewDate.ParentEntityDisplayName = "Performance Reviews";
        _PerformanceReviewDate.DisplayOrder = 2;

        _PerformanceReviewRating = new CustomFieldMetaData(this);
        _PerformanceReviewRating.BaseClass = className;
        _PerformanceReviewRating.CustomFieldDataType = typeof(int);
        _PerformanceReviewRating.CustomFieldName = "ReviewRating";
        _PerformanceReviewRating.CustomFieldDisplayName = "Performance Review Rating";
        _PerformanceReviewRating.ParentEntityDisplayName = "Performance Reviews";
        _PerformanceReviewRating.DisplayOrder = 3;
    }

    public string Name
    {
        get { return "MyProvider"; }
    }

    public string DisplayName
    {
        get { return "My Basic Provider"; }
    }

    public List<ICustomFieldMetaData> GetMetaDataForClass(string className)
    {
        List<ICustomFieldMetaData> metaData = new List<ICustomFieldMetaData>();

        if (className == "HRMS.Ste.BusinessObjects.EmployeePersonnel")
        {
            InitMetaData(className);

            metaData.Add(_ShirtSize);
            metaData.Add(_PerformanceReviewDate);
            metaData.Add(_PerformanceReviewRating);
        }

        return metaData;
    }

    public CustomFieldDataCollection GetCustomData(string className, string pk)
    {
        CustomFieldDataCollection results = new CustomFieldDataCollection(this);

        if (className == "HRMS.Ste.BusinessObjects.EmployeePersonnel" && pk == "101 ZSI") //
        "Donald Adams" in HRMS Sample Data
        {
            InitMetaData(className);
            // First add one-to-one property
            results.EmployeeLevelData = new List<ICustomFieldData>();
            ICustomFieldData shirtSizeData = new CustomFieldData();
            shirtSizeData.MetaData = _ShirtSize;
            shirtSizeData.DataValue = "XL";
            results.EmployeeLevelData.Add(shirtSizeData);

            // Add Multi-row data
            results.MultiRowData = new List<IMultiRowCustomData>();
            IMultiRowCustomData performanceReviewMultiData = new MultiRowCustomData();
            results.MultiRowData.Add(performanceReviewMultiData);
        }
    }

```

```
performanceReviewMultiData.GroupName = _PerformanceReviewDate.ParentEntity;
performanceReviewMultiData.CustomData = new List<List<ICustomFieldData>>();

// Now add the individual multi-row records, starting with the first performance
review
List<ICustomFieldData> row1PerformanceReviewData = new List<ICustomFieldData>();
performanceReviewMultiData.CustomData.Add(row1PerformanceReviewData);

ICustomFieldData row1ReviewRating = new CustomFieldData();
row1ReviewRating.MetaData = _PerformanceReviewRating;
row1ReviewRating.DataValue = 4;
row1PerformanceReviewData.Add(row1ReviewRating);

ICustomFieldData row1ReviewDate = new CustomFieldData();
row1ReviewDate.MetaData = _PerformanceReviewDate;
row1ReviewDate.DataValue = new DateTime(2010, 2, 1);
row1PerformanceReviewData.Add(row1ReviewDate);

// Add the 2nd performance review
List<ICustomFieldData> row2PerformanceReviewData = new List<ICustomFieldData>();
performanceReviewMultiData.CustomData.Add(row2PerformanceReviewData);

ICustomFieldData row2ReviewRating = new CustomFieldData();
row2ReviewRating.MetaData = _PerformanceReviewRating;
row2ReviewRating.DataValue = 5;
row2PerformanceReviewData.Add(row2ReviewRating);

ICustomFieldData row2ReviewDate = new CustomFieldData();
row2ReviewDate.MetaData = _PerformanceReviewDate;
row2ReviewDate.DataValue = new DateTime(2010, 3, 1);
row2PerformanceReviewData.Add(row2ReviewDate);

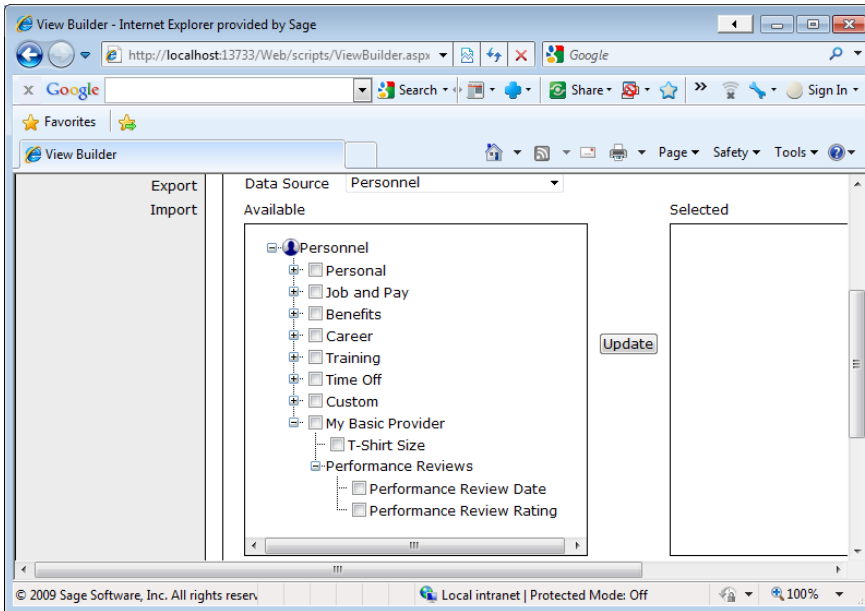

}

return results;
}

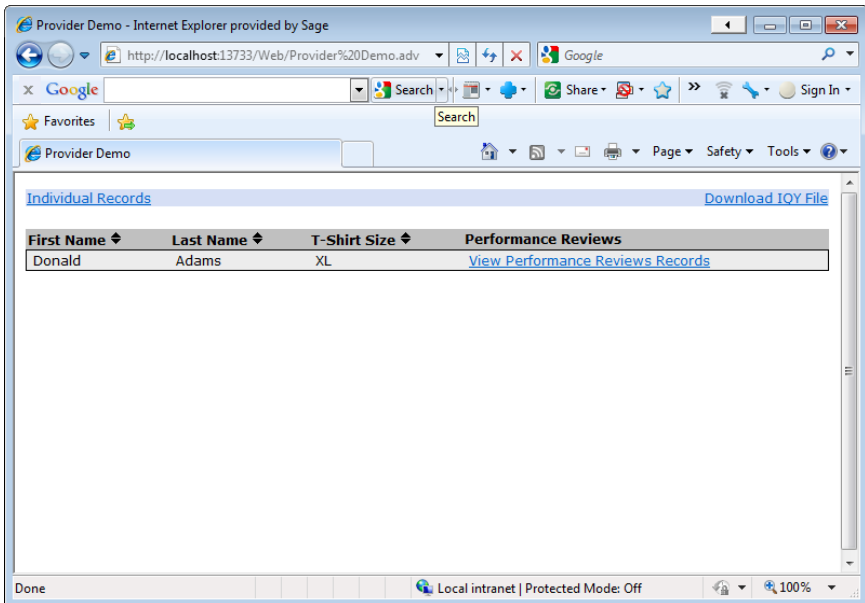

public bool WriteCustomData(string className, string pk, CustomFieldDataCollection customData)
{
    // Not currently implemented

    return true;
}
}
```

If the above code is compiled into an assembly and placed into the **ESS Web\bin** directory, the three additional custom properties (shirt size, performance review date, and performance review rating) will now be available inside of the View Builder grouped by the provider's **DisplayName** property as shown below:

Selecting the three properties (along with the built-in properties for **First Name** and **Last Name**) will cause them to render in a similar manner as existing one-to-one and one-to-many properties as shown in the following figure.

# Sage HRMS Keys used by Sage Employee Self Service

---

## Tables and Keys

This is a list of all the Sage HRMS tables that are used by Sage Employee Self Service. The values in each of these key columns must be unique.

When importing data from a third-party system to Sage HRMS, these key columns must be populated and no two records in these tables should have identical values. If there are any duplicate records, they must be removed so that Sage Employee Self Service can correctly read the data

Table	Alias	Key Columns
